

Correlation vs Causation Study Report

Name : Mohd Huzaifa Ammar

Role : Business Analyst Intern

Date : 05/09/2026

Introduction

Data analysis is one of the most important components of modern decision-making in business, healthcare, finance, marketing, and scientific research. Organizations collect large amounts of data to identify patterns, trends, and relationships that can support strategic planning and operational improvements. One of the most commonly used statistical techniques in exploratory data analysis is correlation analysis.

Correlation analysis helps identify whether two variables move together and measures the strength and direction of their relationship. However, a major challenge in data interpretation is the misunderstanding between correlation and causation. Many analysts and organizations incorrectly assume that if two variables are strongly correlated, one variable must be causing the other. This assumption can lead to incorrect business strategies, flawed predictions, and poor decision-making.

The purpose of this study is to demonstrate the distinction between correlation and causation using a multi-variable dataset. The analysis focuses on identifying relationships between variables, visualizing these relationships using statistical charts, and critically evaluating whether observed correlations indicate causal relationships.

This report uses the Diabetes Dataset from Scikit-Learn, which contains multiple medical attributes and a target variable representing disease progression. The dataset is suitable for statistical analysis because it contains several independent variables that may influence the target outcome.

The study includes:

- Correlation matrix analysis
- Scatter plot visualizations with trend lines
- Interpretation of statistical relationships
- Discussion of causation limitations
- Business and healthcare implications

The objective is not only to identify statistical relationships but also to understand the limitations of correlation analysis and emphasize the importance of careful interpretation.

Objectives of the Study

The primary objectives of this study are:

1. To understand the concept of correlation and its significance in data analysis.
2. To identify relationships between variables using statistical methods.
3. To visualize correlations using heatmaps and scatter plots.
4. To distinguish between correlation and causation.
5. To understand the risks of making causal assumptions from correlated data.

6. To evaluate the business implications of analytical findings.
7. To demonstrate how exploratory data analysis supports data-driven decision-making.

Dataset Description

The analysis uses the Diabetes Dataset available in the Scikit-Learn machine learning library. This dataset is widely used for regression and statistical analysis tasks.

Dataset Characteristics

The dataset contains medical information collected from diabetes patients and includes several physiological variables.

Independent Variables

The dataset includes the following features:

Variable Description

age	Age of the patient
sex	Gender-related variable
bmi	Body Mass Index
bp	Average blood pressure
s1	Total serum cholesterol
s2	Low-density lipoproteins
s3	High-density lipoproteins
s4	Total cholesterol / HDL ratio
s5	Serum triglyceride level
s6	Blood sugar level

Dependent Variable

Variable	Description
disease_progression	Quantitative measure of diabetes disease progression after one year

Why This Dataset Was Selected

This dataset was selected because:

- It contains multiple numerical variables.
- It is suitable for correlation analysis.

- It enables visualization of relationships between health indicators and disease progression.
 - It demonstrates real-world analytical scenarios in healthcare analytics.
-

Data Preprocessing

Before conducting the analysis, the dataset was cleaned and prepared for statistical evaluation.

Steps Performed

1. Loading the Dataset

The dataset was imported using the Scikit-Learn library and converted into a Pandas DataFrame for easier manipulation and analysis.

2. Renaming Variables

The target column was renamed from target to disease_progression to improve readability and interpretation.

3. Data Validation

The dataset was checked for:

- Missing values
- Data type consistency
- Duplicate records

No major preprocessing issues were identified because the dataset is already standardized and cleaned.

Understanding Correlation

Definition of Correlation

Correlation is a statistical measure that describes the degree to which two variables move in relation to one another.

The correlation coefficient ranges from -1 to +1.

Correlation Value Interpretation

+1	Perfect positive correlation
0	No correlation
-1	Perfect negative correlation

Positive Correlation

A positive correlation means that as one variable increases, the other variable also tends to increase.

Example:

- Higher BMI may be associated with higher disease progression.

Negative Correlation

A negative correlation means that as one variable increases, the other tends to decrease.

Example:

- Higher HDL cholesterol may be associated with lower disease risk.

No Correlation

No correlation means there is no observable linear relationship between variables.

Correlation Matrix Analysis

Purpose of the Correlation Matrix

A correlation matrix is used to measure pairwise relationships between variables in the dataset. It provides a numerical summary of how strongly variables are related.

The correlation matrix helps:

- Detect strong relationships
 - Identify weak relationships
 - Support feature selection
 - Detect multicollinearity
 - Guide predictive modeling
-

Correlation Heatmap

Purpose of the Heatmap

A heatmap is a visual representation of correlation values. Different colors represent different strengths of correlation.

The heatmap allows analysts to quickly identify:

- Strong positive correlations
- Strong negative correlations
- Potentially important variables

Interpretation of Results

The heatmap revealed that:

- BMI shows a strong positive relationship with disease progression.
- Blood pressure also demonstrates a moderate positive relationship.
- Some serum measurements exhibit significant relationships with the target variable.

These relationships indicate that certain health indicators may be associated with worsening diabetes progression.

However, these relationships only indicate statistical association and not causality.

Scatter Plot Analysis

Purpose of Scatter Plots

Scatter plots are used to visualize the relationship between two variables.

They help identify:

- Linear trends
- Non-linear patterns
- Outliers
- Data clustering
- Strength of relationships

Trend lines were added to summarize the direction of relationships.

BMI vs Disease Progression

The scatter plot between BMI and disease progression demonstrates a positive trend.

Observations

- Patients with higher BMI values generally tend to show higher disease progression scores.
- The trend line slopes upward, indicating a positive relationship.
- The relationship appears moderately strong.

Interpretation

This suggests that obesity or higher body mass may be associated with worsening diabetic conditions.

However, BMI alone may not directly cause disease progression. Other contributing factors may include:

- Genetics

- Lifestyle
- Diet
- Physical activity
- Medication adherence

Therefore, the analysis supports correlation but does not establish causation.

Blood Pressure vs Disease Progression

The scatter plot between blood pressure and disease progression shows a moderate positive relationship.

Observations

- Higher blood pressure values are associated with increased disease progression.
- The data points show some dispersion, indicating variability.

Interpretation

Blood pressure may influence diabetic complications, but it may also be affected by external factors such as:

- Stress
- Age
- Diet
- Cardiovascular conditions

This relationship alone cannot confirm direct causality.

Serum Measurement (s5) vs Disease Progression

The s5 variable demonstrates one of the strongest relationships with disease progression.

Observations

- The scatter plot indicates a strong upward trend.
- Data points align more closely with the trend line compared to other variables.

Interpretation

This suggests that serum triglyceride levels may be strongly associated with diabetes progression.

However, additional clinical studies would be required to determine whether this variable directly contributes to disease worsening.

Understanding Causation

Definition of Causation

Causation means that one variable directly influences another variable.

For causation to exist:

- Changes in one variable must produce changes in another.
 - The relationship must be scientifically or logically explainable.
 - Alternative explanations must be ruled out.
-

Why Correlation Does Not Imply Causation

One of the most important principles in statistics is that correlation does not imply causation.

Two variables may appear strongly related even when no direct causal relationship exists.

Reasons for Misleading Correlations

1. Confounding Variables

A hidden third variable may influence both variables.

Example:

- Exercise may influence both BMI and disease progression.

2. Reverse Causality

The outcome variable may influence the predictor variable rather than the other way around.

Example:

- Disease severity may influence lifestyle changes and BMI.

3. Coincidental Relationships

Some relationships occur purely by chance without meaningful connection.

Importance of Controlled Experiments

To establish causation, organizations and researchers typically use:

- Controlled experiments
- Randomized trials
- Longitudinal studies
- Causal inference techniques

These methods help isolate variables and remove external influences.

Correlation analysis alone is insufficient for proving causal relationships.

Business Implications

Healthcare Industry Applications

1. Risk Identification

Correlation analysis can help healthcare providers identify high-risk patients.

For example:

- Patients with high BMI and blood pressure may require additional monitoring.

2. Preventive Healthcare

Organizations can use findings to promote:

- Wellness programs
- Dietary improvements
- Fitness initiatives

3. Resource Optimization

Hospitals can allocate resources more effectively by identifying high-risk groups.

4. Predictive Analytics

Correlation analysis supports the development of predictive healthcare models.

These models can assist in:

- Early diagnosis
 - Patient risk scoring
 - Treatment prioritization
-

Limitations of the Study

Despite useful insights, this study has several limitations.

1. Correlation Does Not Confirm Causality

The analysis identifies associations but cannot establish direct cause-and-effect relationships.

2. Limited Dataset Scope

The dataset may not represent all population groups or medical conditions.

3. External Factors Not Included

Variables such as:

- Diet
- Genetics
- Smoking habits
- Physical activity

are not fully represented.

4. Linear Relationship Assumption

Correlation primarily measures linear relationships and may miss non-linear patterns.

Conclusion

This study demonstrated the process of identifying and interpreting statistical relationships using correlation analysis.

The analysis revealed that variables such as BMI, blood pressure, and serum measurements exhibit positive relationships with diabetes progression. Visualizations such as heatmaps and scatter plots helped simplify interpretation and identify important trends.

However, the study also emphasized a critical analytical principle: correlation does not imply causation. Statistical association alone is insufficient to conclude that one variable directly causes another.

Organizations must avoid making strategic decisions based solely on correlated data. Instead, correlation analysis should be treated as an exploratory tool that guides deeper investigation and supports hypothesis generation.

Future studies should incorporate:

- Controlled experiments
- Advanced causal inference methods
- Larger datasets
- Longitudinal analysis

to better understand true causal relationships.

The findings of this study highlight the importance of careful statistical interpretation and responsible data-driven decision-making in modern analytics.
